Hæmorrhage

Threatened or Actual, Controlled by Hemoplastin

HEMOPLASTIN is a sterile fluid derived from normal serum of horses and cattle. It is composed principally of prothrombin and thrombokinase together with a third substance known as anti-antithrombin. These constituents are in physiologically balanced solution ready for immediate use. The preparation keeps well for at least three years.

HEMOPLASTIN, in relatively minute quantity, is remarkably effective as a blood-coagulating agent. Both laboratory and clinical evidence show that its haemostatic power is greater than that of fresh blood serum, brain extracts or extracts of blood platelets, and that its administration is unattended by any untoward effect.

HEMOPLASTIN is indicated in the treatment of all types of haemorrhage, particularly those depending upon imperfect coagulation of the blood. It has proved of great value in pulmonary haemorrhage, purpura haemorrhagica, intestinal bleeding, bleeding of the new-born, and operative haemorrhage—especially in connection with nose and throat work. Its administration to haemophiliac subjects about to undergo surgical or dental operations is a valuable precaution against excessive post-operative bleeding.

HEMOPLASTIN may be administered intravenously or subcutaneously; it may also be applied on sterile gauze to bleeding surfaces.

Hemoplastin is supplied in bulbs containing 2 c.c.
