## DIBROMIN

A POWERFUL  
NEW GERMICIDE

(DI-BROM-MALONYL-UREIDE)

For  
Irrigations,  
Wet Dressings,  
Moist Gauze  
Packings,  
Douches,  
Gargles,  
etc., etc.

DIBROMIN is a white, crystalline synthetic compound containing approximately 56 per cent. of bromine in loose chemical combination. When its solutions are brought into contact with infected tissues, the bromine is slowly liberated, and exerts a destructive oxidising effect on micro-organisms, similar to that produced by chlorine.

Dibromin possesses all the advantages claimed for chlorinated compounds and solutions, and in addition the following:—

*It is stable in dry form: solutions are easily made, are definite in strength, and are non-irritating.*

The phenol coefficient of Dibromin tested on the typhoid bacillus, is 105, and no less than 213 on the *Streptococcus hæmolyticus*. Its solutions do not coagulate serum or tissue albumin, and even a saturated solution in water has proved so innocuous that its toxicity is practically negligible.

The preparation of Dibromin for use consists simply in dissolving the crystals in water, and the ease with which solutions are prepared is in striking contrast with the difficulties experienced in the preparation of certain of the liquid chlorinated compounds.

Supplied in bottles containing either 10 or 50 capsules, each capsule containing 6 grains. Literature and sample will be sent to physicians on request.
